Inequalities and Absolute Value

by Kevin M. Chevalier

Real numbers are ordered where given the real numbers a , b , and c :

$a < b$
 a “**is less than**” b
Ex: $1 < 2$

$c > b$
 c “**is greater than**” b
Ex: $3 > 2$

If a real number is ordered given that b is between a and c from the above example:

$a < b < c$
 b “**is between**” a and c
Ex: $1 < 2 < 3$

In the cases above, the numbers are not included in the interval.

Inequality Properties

For real numbers a , b , c , and constant k .

1. Transitive Property (our above example)

If $a < b$ and $b < c$, then $a < c$

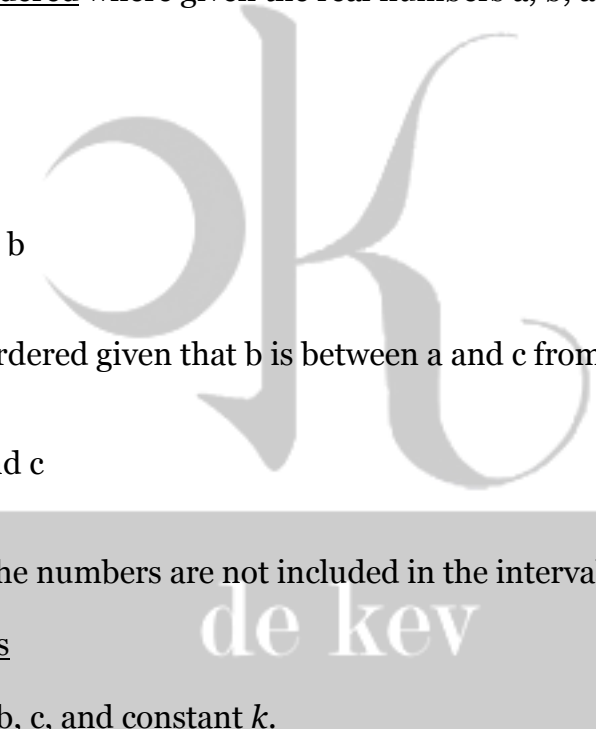

Similarly, if $a \leq b$ and $b \leq c$, then $a \leq c$

2. Converse Property

If $a < b$, then $b > a$ (similarly, if $a \leq b$, then $b \geq a$)

If $a > b$, then $b < a$ (similarly, if $a \geq b$, then $b \leq a$)

3. Addition or Subtraction with a Constant

If $a < b$, then $a + k < b + k$ (similarly, if $a \leq b$, then $a + k \leq b + k$)
If $c > b$, then $c - k > b - k$ (similarly, if $c \geq b$, then $c - k \geq b - k$)

4. Multiplication or Division by a Positive Constant

If $a < b$, then $ak < bk$ (similarly, if $a \leq b$, then $ak \leq bk$)

If $c > b$, then $\frac{c}{k} > \frac{b}{k}$ (similarly, if $c \geq b$, then $\frac{c}{k} \geq \frac{b}{k}$)

5. Multiplication or Division by a Negative Constant

When you multiply or divide an inequality by a negative number, the inequality is reversed.

Example 1.2a: Given the inequality, $-3x \leq 6$ solve for x .

First we divide both sides by -3 :

$$\frac{-3x}{-3} \leq \frac{6}{-3}$$

Then we reverse the inequality:

$$x \geq -2$$

Example 1.2b: Given the inequality, $\frac{x}{-4} > 5$, solve for x .

First we multiply both sides by -4 :

$$\frac{x}{-4} (-4) > 5 (-4)$$

Then we reverse the inequality:

$$x < -20$$

Intervals on the real number line

***For the graphs, see the accompanying inequality graph worksheet.**

In **open intervals**, the endpoints a and b are not included. They are denoted by parentheses (a, b) and when graphed on a number line, the circles are open/hollow.

In **closed intervals**, the endpoints a and b are included. They are denoted by square brackets $[a, b]$ and when graphed on a number line, the circles are closed/solid.

All real numbers

Notation

Set: $(-\infty, \infty)$

Interval: $\{x \mid x \text{ is a real number}\}$

Bounded open interval

Notation

Set: (a, b)

Interval: $\{x \mid a < x < b\}$

Bounded closed interval

Notation

Set: $[a, b]$

Interval: $\{x \mid a \leq x \leq b\}$

Half-closed (half-open) intervals

Notation

Set: $[a, b)$

$(a, b]$

Interval: $\{x \mid a \leq x < b\}$

$\{x \mid a < x \leq b\}$

Unbounded open interval

Notation

Set: $(-\infty, b)$

(a, ∞)

Interval: $\{x \mid x < b\}$

$\{x \mid x > a\}$

Unbounded closed interval

Notation

Set: $(-\infty, b]$

$[a, \infty)$

Interval: $\{x \mid x \leq b\}$

$\{x \mid x \geq a\}$

Solving Inequalities

***Graphs to the solutions for the examples are in the inequality graph worksheet.**

Example 1.2c

Solve the linear inequality $4x + 3 > 15$ and graph its solution on the real number line.

$$4x + 3 > 15$$

$$4x + 3 - 3 > 15 - 3 \quad \text{Subtract 3 from both sides.}$$

$$\frac{4x}{4} > \frac{12}{4}$$

Divide both sides by 4.

$$x > 3$$

Solution

The solution is the set of all x 's such that x is greater than 3; $\{x \mid x > 3\}$. In set notation: $(3, \infty)$. Remember, 3 is not included so on the graph it is denoted by an open circle. Since the values for x are greater than 3, it is unbounded.

Example 1.2d

Solve the linear inequality $-4 \leq 2x + 6 \leq 14$ and graph its solution on the real number line.

$$-4 \leq 2x + 6 \leq 14$$

$$-4 - 6 \leq 2x + 6 - 6 \leq 14 - 6$$

Subtract 6 from all parts.

$$-10 \leq 2x \leq 8$$

$$-\frac{10}{2} \leq \frac{2x}{2} \leq \frac{8}{2}$$

Divide all parts by 2.

$$-5 \leq x \leq 4$$

Solution

The solution set is $[-5, 4]$.

Example 1.2e

Solve the quadratic inequality $x^2 + 6x + 14 \leq 6$ and graph its solution on the real number line.

$$x^2 + 6x + 14 \leq 6$$

$$x^2 + 6x + 14 - 6 \leq 6 - 6$$

Subtract 6 from both sides to change to general form.

$$x^2 + 6x + 8 \leq 0$$

General form

$$(x+4)(x+2) \leq 0$$

Factor

When we solve for x , we get $x = -4$ and $x = -2$. We have to test the signs in each test interval to solve the inequality.

There are three intervals that we need to test:

$(-\infty, -4]$, $[-4, -2]$, and $[-2, \infty)$

Step 1: Choose a number in the interval and compute by replacing the x in the polynomial.

The polynomial: $x^2 + 6x + 8$

Interval	Number Chosen in Interval	Answer
$(-\infty, -4]$	-5	3
$[-4, -2]$	-3	-1
$[-2, \infty)$	0	8

So for the interval $(-\infty, -4]$, we choose -5 and put it in the polynomial to test the sign.

$$\begin{aligned} &(-5)^2 + 6(-5) + 8 \\ &25 - 30 + 8 \\ &3 \end{aligned}$$

The polynomial is positive for all real numbers in the interval $(-\infty, -4]$.

For the interval $[-4, -2]$, we choose -3.

$$\begin{aligned} &(-3)^2 + 6(-3) + 8 \\ &9 - 18 + 8 \\ &-1 \end{aligned}$$

The polynomial is negative for all real numbers in the interval $[-4, -2]$.

For the interval $[-2, \infty)$, we choose 0.

$$\begin{aligned} &(0)^2 + 6(0) + 8 \\ &8 \end{aligned}$$

The polynomial is positive for all real numbers in the interval $[-2, \infty)$.

Step 2: Now we look at the original inequality. In this case, the solution is $[-4, -2]$ since the polynomial is negative for all real numbers in this interval.

Absolute Value and Distance on the Real Number Line

The absolute value of a number can't be negative.

If a is a real number:

$$|a| = \begin{cases} a, & \text{if } a \geq 0 \\ -a, & \text{if } a \leq 0 \end{cases}$$

Example 1.2f: Find the absolute value of -8.

If real number $a = -8$, then $-8 \leq 0$. So, we use $-a$.

$$|-8| = -a = -(-8) = 8$$

Properties of Absolute Value

Let...

a and b be real numbers

n be a positive integer

k be a positive real number

Square root definition:

$$|a| = \sqrt{a^2}$$

Subadditivity:

$$|a + b| \leq |a| + |b|$$

Multiplication:

$$|ab| = |a| |b|$$

Quotient:

$$\left| \frac{a}{b} \right| = \frac{|a|}{|b|}, \quad b \neq 0$$

Powers:

$$|a^n| = |a|^n$$

$$-|a| \leq a \leq |a|$$

$|a| \leq k$ if and only if

$$-k \leq a \leq k$$

$|a| < k$ if and only if

$$-k < a < k$$

$|a| \geq k$ if and only if

$$a \leq -k \text{ or } a \geq k$$

$|a| > k$ if and only if

$$a < -k \text{ or } a > k$$

Solving Absolute Value Inequalities

Example 1.2g: Solve the inequality $|x + 5| < 10$

From the property above we can see that $|a| < k$ if and only if $-k < a < k$

Therefore, we apply this to our inequality:

$$-10 < x + 5 < 10$$

$$-10 - 5 < x + 5 - 5 < 10 - 5 \quad \text{Subtract 5 from all parts}$$

$$-15 < x < 5$$

Solution

The solution set is the single interval $(-15, 5)$.

Example 1.2h: Solve the inequality $|x + 6| \geq 8$

From the property above we can see that $|a| \geq k$ if and only if $a \leq -k$ or $a \geq k$

Therefore, we apply this to our inequality:

$$x + 6 \leq -8 \text{ or } x + 6 \geq 8$$

$$\text{For } x + 6 \leq -8, \quad x \leq -14$$

$$\text{For } x + 6 \geq 8, \quad x \geq 2$$

The solution set is the union of the disjointed intervals $(-\infty, -14]$ and $[2, \infty)$.

Distance and Midpoint

Distance between two points with real numbers a and b:

$$d = |a - b| = |b - a|$$

Example 1.2i: Find the distance between -6 and 3.

Let $a = -6$ and $b = 3$

$$d = |a - b| = |-6 - 3| = |-9| = 9$$

In both directions, -6 and 3 are 9 units from each other.

From a to b (going left to right), the directed distance would be 9. This is the directed distance from a to b. To compute, we use $b - a$. In this example, $3 - (-6)$ which would be $3 + 6$ to get 9.

From b to a (going right to left), the directed distance would be -9. This is the directed distance from b to a. To compute, we use $a - b$. In this example, $-6 - 3$ to get -9.

The midpoint is the average value of endpoints a and b.

The midpoint of interval (a, b):

$$\frac{a + b}{2}$$

Example 1.2j: Find the midpoint of the interval [4, 16]

Let $a = 4$ and $b = 16$

$$\frac{4 + 16}{2} = \frac{20}{2} = 10$$
